Vol. 11, No. 48

PROVISIONAL INFORMATION ON SELECTED NOTIFIABLE DISEASES IN THE UNITED STATES AND ON DEATHS IN SELECTED CITIES FOR WEEK ENDED DECEMBER 1, 1962

POLIOMYELITIS — The week ending December 1, 1962, accounted for 20 cases of poliomyelitis (18 paralytic). The total for the comparable week in 1961 was 18 cases (13 paralytic).

Cases this week were of scattered origin, being reported from fourteen States. Only Louisiana and West Virginia reported as many as three cases. No new case concentrations have been noted among the States reporting, many delayed reports being evident.

Cumulative totals for poliomyelitis incidence through the 48th week this year remain below those for any previous year. The comparable figures for 1962 and the previous four years are shown in the following tabulation:

POLIOMYELITIS (1ST THROUGH 48TH WEEK) 1958-1962

	1962	1961	1960	1959	1958
Paralytic	663	835	2,182	5,468	2,950
Total	833	1,280	3,121	8,243	5,775

The number of cases for the previous 6 weeks, ending December 1, 1962, is compared to similar periods for the previous four years in the table below:

POLIOMYELITIS (43RD THROUGH 48TH WEEK) 1958-1962

	1962	1961	1960	1959	1958
Paralytic	111	135	332	759	650
Total	136	194	441	1,039	1,031

EPIDEMIOLOGICAL REPORTS

Tularemia - Wisconsin

During the past year, several tularemia infections have occurred among Wisconsin mink ranchers, muskrat farmers, and beaver trappers.

A mink rancher and his helper were hospitalized with tularemia near Woodruff, Wisconsin, during March. The owner of the ranch found a lesion on the dorsum of his fourth finger. He developed a temperature of 103°F, with lymphangitis and adenitis. Serum tests were negative eight days after the first symptoms, but agglutinins to tularemia developed to a titer of 1280 at 29 days, and to 2560 at 35 days.

Three weeks later his helper was also hospitalized with a large lesion on the left thumb and tenderness and swelling in the axillary nodes. His serum had a titer of 160 to tularemia at 5 days and 5120 at 17 days. Both patients recovered after treatment with streptomycin. Two other workers on the mink ranch did not develop clinical symptoms and tests on their sera were negative.

Several sick mink on the ranch were examined. Seven out of ten mink sera tested showed high agglutinin titers and the tularemia organism was isolated from the mink tissues by the Communicable Disease Center, Atlanta, Georgia. The most likely source of the infection was believed to be frozen jackrabbit meat which had been shipped in from out of State for mink food.

A seven-year-old New London, Wisconsin, boy was infected during April after helping flesh a muskrat on his father's fur farm. A lesion developed on the little finger of his left hand, which he had also previously skinned on a doorknob. He soon had a temperature of 103.8°F, with pain and enlargement in the lymph nodes in his left arm. His serum had agglutinins to tularemia of 640 at 26 days, 2560 at 44 days, 640 at 66 days, and 320 after 78 days. He made a prompt recovery with treatment.

Tests on his father's serum showed a titer of 320, although his only history of known infection was eight years ago. The 12-year-old brother's serum had a titer of 640, and the serum of a part-time helper on the fur farm was 320. Neither of these two had a history of known infection. The boy's mother had no history of infection and her serum was negative.

During September, sera were collected from twelve other muskrat fur farmers. Three of these twelve had agglutinins, with titers of 40, 80, and 160, indicating past infections. These were all negative to brucella.

During June a Conservation Department beaver trapper was hospitalized in Marshfield for four days with a temperature that rose to 104°F, pain and swelling in lymph nodes, and a lesion on the little finger of his

right hand. His serum had a titer of 40 at 11 days, which increased to 320 at 27 days.

(Abstracted from Laboratory Newsletter, Wisconsin State Laboratory of Hygiene.)

Salmonella Typhimurium Outbreak - Humans and Cattle - Wisconsin

An outbreak of *Salmonella typhimurium*, which involved seven cows and six members of the family living on the farm, has been reported from Door County, Wisconsin.

The first illness occurred about October 1 in a two-year-old Holstein cow which developed high fever and explosive diarrhea, and died in a few days. On October 13, a second cow in the herd of 79 developed high fever, bloody diarrhea and anorexia, and also succumbed to the illness. *S. typhimurium* was isolated from a stool culture. Five additional cows subsequently developed diarrhea and slight temperature but recovered.

The 38-year-old owner of the herd experienced a four-day diarrheal illness between the time of the death of the first cow and onset of illness in the second. His wife and parents also experienced mild diarrheal illnesses; however, two children, ages 8 and 11 years, remained symptom free. *S. typhimurium* was isolated from the stool specimens of all six family members.

No new animals had been introduced into the herd during the previous year. Most of the grain for feed is raised on the farm, although some ground corn and minerals are added as supplements. Samples of the feed were negative by culture. Sanitary conditions on the farm were reported to be excellent.

No other known cases have occurred either in cattle or humans in the county this year.

A similar *S. typhimurium* outbreak, involving six bovine and two human cases, occurred in Wisconsin in September, 1958 (MMWR, Vol. 8, No. 7, 1959).

(Reported by Miss Estelle Fidler, R.N., Public Health Nursing Service, Door County, Wisconsin, and Josef Prezler, M.D., Director, Bureau of Communicable Disease, Wisconsin State Board of Health.)

Clostridium perfringens Food Poisoning - Philadelphia

On the evening of October 20, 140 children and 15 employees of a city welfare center became ill with severe diarrhea and abdominal pain, but little nausea or vomiting. The suspect meal, a noon dinner, was consumed by 170 persons. It consisted of roast beef, gravy, vegetables and beverage. Symptoms developed between 8 and 12 hours after eating. *Clostridium perfringens* organisms in large numbers were isolated from both the roast beef and the gravy; none were isolated from the vegetables.

The roast beef and gravy had been prepared the day previous to the meal and allowed to cool in open trays without refrigeration for approximately 22 hours. A few hours before serving, the meat and gravy had been warmed separately at low temperatures in large pans.

(Reported by Dr. Milton Werrin, Chief, Veterinary Public Health Section, Philadelphia Department of Public Health, and Ernest J. Witte, D.V.M., Chief, Veterinary Public Health Section, Pennsylvania State Department of Health).

INTERNATIONAL NOTES - QUARANTINE MEASURES
